Team 1 M3 Feedback

Last week, we conducted a demo of our app. We need to implement messaging, comments on posts, and maps. We discussed how we needed to work on account functionalities and fixing issues with the post search when no items meet the filter criteria. Our biggest bug with accounts was cookies sending cookies from backend to the front end. To solve this we figured out that HTTPS was required to send cookies to a different url since our product runs using 2 urls; therefore, HTTP cannot be used for our app. We also discussed that when we try to filter posts and no results return and the application crashes. To solve this issue, we had to switch our data mapping protocol on the frontend from checking if data exists to working with the data provided by the backend.
